**Prof. Olga Veksler**

**Lecture 15**  
Unsupervised Learning and  
Clustering

**Supervised vs. Unsupervised Learning**

- Up to now we considered **supervised learning** scenario, where we are given
  - samples  $x_1, \dots, x_n$
  - class labels for all samples  $x_1, \dots, x_n$
  - This is also called learning with teacher, since correct answer (the true class) is provided
- In the next few lectures we consider **unsupervised learning** scenario, where we are only given
  - samples  $x_1, \dots, x_n$
  - This is also called learning without teacher, since correct answer is not provided
  - do not split data into training and test sets

**Today**

- New Topic: **Unsupervised Learning**
  - Supervised vs. unsupervised learning
  - Unsupervised learning
    - Next Time: parametric unsupervised learning
    - Today: nonparametric unsupervised learning = clustering
      - Proximity Measures
      - Criterion Functions
      - Flat Clustering
        - k-means
      - Hierarchical Clustering
        - Divisive
        - Agglomerative

**Unsupervised Learning**

- Data is *not* labeled

a lot is known  
"easier"

- Parametric Approach**
  - assume parametric distribution of data
  - estimate parameters of this distribution
  - much "harder" than supervised case
- NonParametric Approach**
  - group the data into **clusters**, each cluster (hopefully) says something about categories (classes) present in the data

little is known  
"harder"

## Why Unsupervised Learning?

- Unsupervised learning is harder
  - How do we know if results are meaningful? No answer labels are available.
    - Let the expert look at the results (external evaluation)
    - Define an objective function on clustering (internal evaluation)
- We nevertheless need it because
  1. Labeling large datasets is very costly (speech recognition)
    - sometimes can label only a few examples by hand
  2. May have no idea what/how many classes there are (data mining)
  3. May want to use clustering to gain some insight into the structure of the data before designing a classifier
    - Clustering as data description

## What we Need for Clustering

1. Proximity measure, either
  - similarity measure  $s(x_i, x_k)$ : large if  $x_i, x_k$  are similar
  - dissimilarity (or distance) measure  $d(x_i, x_k)$ : small if  $x_i, x_k$  are similar

large  $d$ , small  $s$

large  $s$ , small  $d$

2. Criterion function to evaluate a clustering

good clustering

bad clustering

3. Algorithm to compute clustering
  - For example, by optimizing the criterion function

## Clustering

- Seek "natural" clusters in the data

- What is a good clustering?
  - internal (within the cluster) distances should be small
  - external (intra-cluster) should be large
- Clustering is a way to discover new categories (classes)

## How Many Clusters?

- Possible approaches
  1. fix the number of clusters to  $k$
  2. find the best clustering according to the criterion function (number of clusters may vary)

## Proximity Measures

- good proximity measure is VERY application dependent
- Clusters should be invariant under the transformations "natural" to the problem
- For example for object recognition, should have invariance to rotation

- For character recognition, no invariance to rotation

## Similarity Measures

- Cosine similarity:

$$s(x_i, x_j) = \frac{x_i^T x_j}{\|x_i\| \|x_j\|}$$

- the smaller the angle, the larger the similarity
- scale invariant measure
- popular in text retrieval

- Correlation coefficient

- popular in image processing

$$s(x_i, x_j) = \frac{\sum_{k=1}^d (x_i^{(k)} - \bar{x}_i)(x_j^{(k)} - \bar{x}_j)}{\left[ \sum_{k=1}^d (x_i^{(k)} - \bar{x}_i)^2 \sum_{k=1}^d (x_j^{(k)} - \bar{x}_j)^2 \right]^{1/2}}$$

## Distance (dissimilarity) Measures

- Euclidean distance

$$d(x_i, x_j) = \sqrt{\sum_{k=1}^d (x_i^{(k)} - x_j^{(k)})^2}$$

- translation invariant

- Manhattan (city block) distance

$$d(x_i, x_j) = \sum_{k=1}^d |x_i^{(k)} - x_j^{(k)}|$$

- approximation to Euclidean distance, cheaper to compute

- Chebyshev distance

$$d(x_i, x_j) = \max_{1 \leq k \leq d} |x_i^{(k)} - x_j^{(k)}|$$

- approximation to Euclidean distance, cheapest to compute

## Feature Scale

- old problem: how to choose appropriate relative scale for features?

- [length (in meters or cms?), weight (in grams or kgs?)]
- In supervised learning, can normalize to zero mean unit variance with no problems
- in clustering this is more problematic, **if variance in data is due to cluster presence, then normalizing features is not a good thing**

before normalization

after normalization

### Simplest Clustering Algorithm

- Having defined a proximity function, can develop a simple clustering algorithm
  - go over all sample pairs, and put them in the same cluster if the distance between them is less than some threshold distance  $d_0$  (or if similarity is larger than  $s_0$ )
  - Pros: simple to understand and implement
  - Cons: very dependent on  $d_0$  (or  $s_0$ ), automatic choice of  $d_0$  (or  $s_0$ ) is not an easily solved issue

### SSE Criterion Function

- Let  $n_i$  be the number of samples in  $D_i$ , and define the mean of samples in  $D_i$

$$\mu_i = \frac{1}{n_i} \sum_{x \in D_i} x$$

- Then the sum-of-squared errors criterion function (to minimize) is:

$$J_{SSE} = \sum_{i=1}^c \sum_{x \in D_i} \|x - \mu_i\|^2$$

- Note that the number of clusters,  $c$ , is fixed

### Criterion Functions for Clustering

- Have samples  $x_1, \dots, x_n$
- Suppose partitioned samples into  $c$  subsets  $D_1, \dots, D_c$

- There are approximately  $c^n/c!$  distinct partitions
- Can define a criterion function  $J(D_1, \dots, D_c)$  which measures the quality of a partitioning  $D_1, \dots, D_c$
- Then the clustering problem is a well defined problem
  - the optimal clustering is the partition which optimizes the criterion function

### SSE Criterion Function

$$J_{SSE} = \sum_{i=1}^c \sum_{x \in D_i} \|x - \mu_i\|^2$$

- SSE criterion appropriate when data forms compact clouds that are relatively well separated

- SSE criterion favors equally sized clusters, and may not be appropriate when "natural" groupings have very different sizes

### Failure Example for $J_{SSE}$

larger  $J_{SSE}$       smaller  $J_{SSE}$

- The problem is that one of the “natural” clusters is not compact (the outer ring)

### Maximum Distance Criterion

- Consider  $J_{max} = \sum_{i=1}^c n_i \left[ \max_{y \in D_i, x \in D_i} \|x - y\|^2 \right]$
- Solves previous case
- However  $J_{max}$  is not robust to outliers

smallest  $J_{max}$       smallest  $J_{max}$

### Other Minimum Variance Criterion Functions

- We can eliminate constant terms from  $J_{SSE} = \sum_{i=1}^c \sum_{x \in D_i} \|x - \mu_i\|^2$
- We get an equivalent criterion function:  $J_E = \frac{1}{2} \sum_{i=1}^c n_i \left[ \frac{1}{n_i^2} \sum_{y \in D_i, x \in D_i} \|x - y\|^2 \right]$   
 $d_i = \text{average Euclidian distance between all pairs of samples in } D_i$
- Can obtain other criterion functions by replacing  $\|x - y\|^2$  by any other measure of distance between points in  $D_i$
- Alternatively can replace  $d_i$  by the median, maximum, etc. instead of the average distance

### Other Criterion Functions

- Recall definition of scatter matrices
  - scatter matrix for  $i$ th cluster  $s_i = \sum_{x \in D_i} (x - \mu_i)(x - \mu_i)'$
  - within the cluster scatter matrix  $S_w = \sum_{i=1}^c s_i$
- Determinant of  $S_w$  roughly measures the square of the volume
- Assuming  $S_w$  is nonsingular, define determinant criterion function:  $J_d = |S_w| = \left| \sum_{i=1}^c s_i \right|$
- $J_d$  is invariant to scaling of the axis, and is useful if there are unknown irrelevant linear transformations of the data

### Iterative Optimization Algorithms

- Now have both proximity measure and criterion function, need algorithm to find the optimal clustering
- Exhaustive search is impossible, since there are approximately  $c^n/c!$  possible partitions
- Usually some iterative algorithm is used
  - Find a reasonable initial partition
  - Repeat: move samples from one group to another s.t. the objective function  $J$  is improved

### K-means Clustering

- We now consider an example of iterative optimization algorithm for the special case of  $J_{SSE}$  objective function

$$J_{SSE} = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

- for a different objective function, we need a different optimization algorithm, of course
- Fix number of clusters to  $k$  ( $c = k$ )
- $k$ -means is probably the most famous clustering algorithm
  - it has a smart way of moving from current partitioning to the next one

### Iterative Optimization Algorithms

- Iterative optimization algorithms are similar to gradient descent
  - move in the direction of descent (ascent), but not in the steepest descent direction since have no derivative of the objective function
  - solution depends on the initial point
  - cannot find global minimum
- Main Issue
  - How to move from current partitioning to the one which improves the objective function

### K-means Clustering

$k = 3$

- Initialize
  - pick  $k$  cluster centers arbitrary
  - assign each example to closest center
- compute sample means for each cluster
- reassign all samples to the closest mean
- if clusters changed at step 3, go to step 2

### K-means Clustering

- Consider steps 2 and 3 of the algorithm
- 2. compute sample means for each cluster

$$J_{SSE} = \sum_{i=1}^k \sum_{x \in D_i} \|x - \mu_i\|^2$$

= sum of

- 3. reassign all samples to the closest mean

If we represent clusters by their old means, the error has gotten smaller

### K-means Clustering

- We just proved that by doing steps 2 and 3, the objective function goes down
- in two step, we found a "smart " move which decreases the objective function
- Thus the algorithm converges after a finite number of iterations of steps 2 and 3
- However the algorithm is not guaranteed to find a global minimum

2-means gets stuck here

global minimum of  $J_{SSE}$

### K-means Clustering

- 3. reassign all samples to the closest mean

If we represent clusters by their old means, the error has gotten smaller

- However we represent clusters by their new means, and mean is always the smallest representation of a cluster

$$\frac{\partial}{\partial z} \sum_{x \in D_i} \frac{1}{2} \|x - z\|^2 = \frac{\partial}{\partial z} \sum_{x \in D_i} \frac{1}{2} (\|x\|^2 - 2x^T z + \|z\|^2) = \sum_{x \in D_i} (-x + z) = 0$$

$$\Rightarrow z = \frac{1}{n_i} \sum_{x \in D_i} x$$

### K-means Clustering

- Finding the optimum of  $J_{SSE}$  is NP-hard
- In practice, k-means clustering performs usually well
- It is very efficient
- Its solution can be used as a starting point for other clustering algorithms
- Still 100's of papers on variants and improvements of k-means clustering every year

### Hierarchical Clustering

- Up to now, considered "flat" clustering

- For some data, hierarchical clustering is more appropriate than "flat" clustering

- Hierarchical clustering

### Hierarchical Clustering: Dendrogram

- preferred way to represent a hierarchical clustering is a dendrogram

- Binary tree
- Level  $k$  corresponds to partitioning with  $n-k+1$  clusters
- if need  $k$  clusters, take clustering from level  $n-k+1$
- If samples are in the same cluster at level  $k$ , they stay in the same cluster at higher levels
- dendrogram typically shows the similarity of grouped clusters

### Hierarchical Clustering: Biological Taxonomy

### Hierarchical Clustering: Venn Diagram

- Can also use Venn diagram to show hierarchical clustering, but similarity is not represented quantitatively

### Hierarchical Clustering

- Algorithms for hierarchical clustering can be divided into two types:
  - Agglomerative (bottom up) procedures
    - Start with  $n$  singleton clusters
    - Form hierarchy by merging most similar clusters

- Divisive (top bottom) procedures
  - Start with all samples in one cluster
  - Form hierarchy by splitting the "worst" clusters

### Agglomerative Hierarchical Clustering

initialize with each example in singleton cluster  
**while** there is more than 1 cluster  
 1. find 2 nearest clusters  
 2. merge them

- Four common ways to measure cluster distance
  - minimum distance  $d_{\min}(D_i, D_j) = \min_{x \in D_i, y \in D_j} \|x - y\|$
  - maximum distance  $d_{\max}(D_i, D_j) = \max_{x \in D_i, y \in D_j} \|x - y\|$
  - average distance  $d_{\text{avg}}(D_i, D_j) = \frac{1}{n_i n_j} \sum_{x \in D_i} \sum_{y \in D_j} \|x - y\|$
  - mean distance  $d_{\text{mean}}(D_i, D_j) = \|\mu_i - \mu_j\|$

### Divisive Hierarchical Clustering

- Any "flat" algorithm which produces a fixed number of clusters can be used
  - set  $c = 2$

### Single Linkage or Nearest Neighbor

- Agglomerative clustering with minimum distance  
 $d_{\min}(D_i, D_j) = \min_{x \in D_i, y \in D_j} \|x - y\|$

- generates minimum spanning tree
- encourages growth of elongated clusters
- disadvantage: very sensitive to noise

what we want at level with  $c=3$

what we get at level with  $c=3$

### Complete Linkage or Farthest Neighbor

- Agglomerative clustering with maximum distance

$$d_{\max}(D_i, D_j) = \max_{x \in D_i, y \in D_j} \|x - y\|$$

- encourages compact clusters

- Does not work well if elongated clusters present

- $d_{\max}(D_1, D_2) < d_{\max}(D_2, D_3)$
- thus  $D_1$  and  $D_2$  are merged instead of  $D_2$  and  $D_3$

### Agglomerative vs. Divisive

- Agglomerative is faster to compute, in general
- Divisive may be less "blind" to the global structure of the data

#### Divisive

when taking the first step (split), have access to all the data; can find the best possible split in 2 parts

#### Agglomerative

when taking the first step merging, do not consider the global structure of the data, only look at pairwise structure

### Average and Mean Agglomerative Clustering

- Agglomerative clustering is more robust under the average or the mean cluster distance

$$d_{\text{avg}}(D_i, D_j) = \frac{1}{n_i n_j} \sum_{x \in D_i} \sum_{y \in D_j} \|x - y\|$$

$$d_{\text{mean}}(D_i, D_j) = \|\mu_i - \mu_j\|$$

- mean distance is cheaper to compute than the average distance
- unfortunately, there is not much to say about agglomerative clustering theoretically, but it does work reasonably well in practice

### First (?) Application of Clustering

- John Snow, a London physician plotted the location of cholera deaths on a map during an outbreak in the 1850s.
- The locations indicated that cases were clustered around certain intersections where there were polluted wells -- thus exposing both the problem and the solution.

From: Nina Mishra HP Labs

### Application of Clustering

- Astronomy
  - SkyCat: Clustered  $2 \times 10^9$  sky objects into stars, galaxies, quasars, etc based on radiation emitted in different spectrum bands.

From: Nina Mishra HP Labs

### Applications of Clustering

- Image Database Organization
  - for efficient search

### Applications of Clustering

- Image segmentation
  - Find interesting "objects" in images to focus attention at

From: Image Segmentation by Nested Cuts, O. Veksler, CVPR2000

### Applications of Clustering

- Data Mining
  - Technology watch
    - Derwent Database, contains all patents filed in the last 10 years worldwide
    - Searching by keywords leads to thousands of documents
    - Find clusters in the database and find if there are any emerging technologies and what competition is up to
  - Marketing
    - Customer database
    - Find clusters of customers and tailor marketing schemes to them

## Applications of Clustering

- gene expression profile clustering
  - similar expressions, expect similar function

## Summary

- Clustering (nonparametric unsupervised learning) is useful for discovering inherent structure in data
- Clustering is immensely useful in different fields
- Clustering comes naturally to humans (in up to 3 dimensions), but not so to computers
- It is very easy to design a clustering algorithm, but it is very hard to say if it does anything good
- General purpose clustering does not exist, for best results, clustering should be tuned to application at hand

## Applications of Clustering

- Profiling Web Users
  - Use web access logs to generate a feature vector for each user
  - Cluster users based on their feature vectors
  - Identify common goals for users
    - Shopping
    - Job Seekers
    - Product Seekers
    - Tutorials Seekers
  - Can use clustering results to improving web content and design

## Agglomerative vs. Divisive

- Agglomerative is faster to compute, in general
- Divisive may be less "blind" to the global structure of the data

### Divisive

when taking the first step (split), have access to all the data; can find the best possible split in 2 parts

### Agglomerative

when taking the first step merging, do not consider the global structure of the data; only look at pairwise structure

### ***Summary***

---

- Clustering (nonparametric learning) is useful for discovering inherent structure in data
- Clustering is immensely useful in different fields
- Clustering comes naturally to humans (in up to 3 dimensions), but not so to computers
- It is very easy to design a clustering algorithm, but it is very hard to say if it does anything good
- General purpose clustering is unlikely to exist, for best results, clustering should be tuned to application at hand
