# On The Parallelization of Triangular Decompositions 

Mohammadali Asadi, Alexander Brandt, Robert H. C. Moir, Marc Moreno Maza, Yuzhen Xie<br>Ontario Research Center for Computer Algebra<br>Department of Computer Science<br>University of Western Ontario, Canada

ISSAC 2020, September 7, 2020

## Outline

1 Introduction

2 Preliminaries

3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Decomposing a Non-Linear System

Many ways to "solve" a system

$$
\left\{\begin{array} { l } 
{ x ^ { 2 } + y + z = 1 } \\
{ x + y ^ { 2 } + z = 1 } \\
{ x + y + z ^ { 2 } = 1 }
\end{array} \quad \stackrel { \text { Gröbner Basis } } { \Longrightarrow } \left\{\begin{array}{r}
x+y+z^{2}=1 \\
(y+z-1)(y-z)=0 \\
z^{2}\left(z^{2}+2 y-1\right)=0 \\
z^{2}\left(z^{2}+2 z-1\right)(z-1)^{2}=0
\end{array}\right.\right.
$$

Triangular Decomposition

$$
\left\{\begin{array}{r}
x-z=0 \\
y-z=0 \\
z^{2}+2 z-1=0
\end{array},\left\{\begin{array}{r}
x=0 \\
y=0 \\
z-1=0
\end{array}, \quad\left\{\begin{array}{r}
x=0 \\
y-1=0 \\
z=0
\end{array}, \quad\left\{\begin{array}{r}
x-1=0 \\
y=0 \\
z=0
\end{array}\right.\right.\right.\right.
$$

Both solutions are equivalent (via a union).
$\rightarrow$ by using triangular decomposition, multiple components are found, suggesting possible component-level parallelism

## Incremental Decomposition of a Non-Linear System

$$
\begin{aligned}
& F=\left\{\begin{array}{l}
x^{2}+y+z=1 \\
x+y^{2}+z=1 \\
x+y+z^{2}=1
\end{array}\right. \\
& F[1] \quad \begin{array}{c}
\varnothing \\
\downarrow
\end{array} \\
& \left\{x^{2}+y+z=1\right\} \\
& F[2] \quad \downarrow \\
& \left\{\begin{array}{r}
x+y^{2}+z=1 \\
y^{4}+(2 z-2) y^{2}+y+\left(z^{2}-z\right)=0
\end{array}\right\} \\
& F[3] \\
& \left\{\begin{array}{rl}
x-z & =0 \\
y-z & =0 \\
z^{2}+2 z-1 & =0
\end{array},\left\{\begin{array}{r}
x \\
y
\end{array}=0, ~\left(\begin{array}{rl}
x & =0 \\
z-1 & =0
\end{array},\left\{\begin{array}{rl}
x-1 & =0 \\
y-1 & =0 \\
z & =0
\end{array},\left\{\begin{aligned}
& x-1 \\
& z=0
\end{aligned}\right.\right.\right.\right.\right.
\end{aligned}
$$

Our Goal: take advantage of different components to gain better performance in high-level decomposition algorithms via parallelism

## Motivations and Challenges

- Many challenges exist in parallelizing triangular decompositions:
$\hookrightarrow$ Some systems never split
$\hookrightarrow$ Some split only at the final step, leaving very little concurrency
$\hookrightarrow$ Some split into one "main" component and several degenerative cases
- Potential parallelism is problem-dependent and not algorithmic; it exhibits irregular parallelism
- Where a splitting is found in an intermediate step, subsequent steps can operate concurrently on each independent component
$\hookrightarrow$ Finding splittings in the geometry is as difficult as solving the system
- A solution must exploit all possible parallelism, without adding too much overhead in the cases where there is none

## A more interesting example (1/2)

$$
\left\{\begin{array}{r}
x+z^{2}+1 \\
5 y+1 \\
5 w-1
\end{array}\right\}, \quad\left\{\begin{array}{r}
5 y+1 \\
z \\
5 w-1
\end{array}\right\}, \quad\left\{\begin{array}{r}
x+z^{2}+1 \\
y \\
w
\end{array}\right\},\left\{\begin{array}{c}
y \\
z \\
w
\end{array}\right\}
$$

$F[4]$

$$
\left\{\begin{array}{r}
x+z^{2}+1 \\
5 y+1 \\
z^{8}+\cdots \\
5 w-1
\end{array},\left\{\begin{array}{r}
x-z \\
5 y+1 \\
z^{2}+z+1 \\
5 w-1
\end{array},\left\{\begin{array}{r}
x \\
5 y+1 \\
z^{\prime} \\
5 w-1
\end{array}, \quad\left\{\begin{array}{r}
x^{2}+1 \\
5 y+1 \\
z w-1 \\
z
\end{array},\left\{\begin{array}{r}
x+z^{2}+1 \\
y \\
z^{8}+\cdots \\
w
\end{array},\left\{\begin{array}{r}
x-z \\
y \\
z^{2}+z+1 \\
w
\end{array},\left\{\begin{array}{r}
x^{2}+1 \\
y \\
z^{\prime} \\
w
\end{array},\left\{\begin{array}{r}
x \\
y \\
z \\
w
\end{array}\right.\right.\right.\right.\right.\right.\right.\right.
$$

## A more interesting example $(2 / 2)$

Sys2913 Component Tree

$\rightarrow$ more parallelism exposed as more components found
$\rightarrow$ yet, work unbalanced between branches
$\rightarrow$ mechanism needed for dynamic parallelism: "workpile" or "task pool"

## Previous Works

- Parallelization of high-level algebraic and geometric algorithms was more common roughly 30 years ago
$\hookrightarrow$ Such as in Gröbner Bases [1, 3, 4] and CAD [10]
- Recent work on parallelism has been on low-level routines with regular parallelism:
$\hookrightarrow$ Polynomial arithmetic [5, 7]
$\hookrightarrow$ Modular methods for GCDs and Factorization [6, 8]
- Recently, high-level algorithms, often with irregular parallelism have neither seen much attention nor received thorough parallelization
$\hookrightarrow$ The normalization algorithm of [2] finds components serially, then processes each component with a simple parallel map
$\hookrightarrow$ Early work on parallel triangular decomposition was limited by symmetric multi-processing and inter-process communication [9]

## Main Results

- An implementation of triangular decomposition fully in $\mathrm{C} / \mathrm{C}++$
- Parallelization effectively exploits as much parallelism as possible throughout the triangular decomposition algorithm
- Implementation framework for parallelization based on task pools, generating functions, pipelines, fork-join
- An extensive evaluation of our implementation against over 3000 real-world polynomial systems

## Outline

## 1 Introduction

2 Preliminaries

## 3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Regular Chains, Notations

Let $\mathbf{k}$ be a perfect field, and $\mathbf{k}[\underline{X}]$ have ordered vars. $\underline{X}=X_{1}<\cdots<X_{n}$
A triangular set $T$ is a regular chain if $h$ is regular modulo $\operatorname{sat}\left(T_{v}^{-}\right)$and $T_{v}^{-}$ is a regular chain

Example:

$$
\begin{aligned}
T & =\left\{\begin{array}{r}
(2 y+b a) x-b y+a^{2} \\
2 y^{2}-b y-a^{2} \\
a+b
\end{array}\right\} \\
& \subset \mathbb{Q}[b<a<y<x]
\end{aligned}
$$

Saturated ideal of a regular chain:

$$
\begin{aligned}
& \rightarrow \operatorname{sat}(T)=\left(\operatorname{sat}\left(T_{v}^{-}\right)+\left\langle T_{v}\right\rangle\right):\langle h\rangle^{\infty} \\
& \rightarrow \operatorname{sat}(\varnothing)=\langle 0\rangle
\end{aligned}
$$

Quasi-component of a regular chain:

$$
\begin{aligned}
& \rightarrow W(T):=V(T) \backslash V\left(h_{T}\right), h_{T}:=\prod_{p \in T} h_{p} \\
& \rightarrow \overline{W(T)}=V(\operatorname{sat}(T))
\end{aligned}
$$

## Triangular Decomposition Algorithms

A triangular decomposition of an input system $F \subseteq \mathbf{k}[\underline{X}]$ is a set of regular chains $T_{1}, \ldots, T_{e}$ such that:
(a) $V(F)=\bigcup_{i=1}^{e} \overline{W\left(T_{i}\right)}$, in the sense of Kalkbrener, or
(b) $V(F)=\bigcup_{i=1}^{e} W\left(T_{i}\right)$, in the sense of Wu and Lazard

Triangular decomposition by incremental intersection has key subroutines:
Intersect. Given $p \in \mathbf{k}[\underline{X}], T \subset \mathbf{k}[\underline{X}]$, compute $T_{1}, \ldots, T_{e}$ such that:
$V(p) \cap W(T) \subseteq \cup_{i=1}^{e} W\left(T_{i}\right) \subseteq V(p) \cap \overline{W(T)}$
Regularize: Given $p \in \mathbf{k}[\underline{X}], T \subset \mathbf{k}[\underline{X}]$, compute $T_{1}, \ldots, T_{e}$ such that:
i. $W(T) \subseteq \cup_{i=1}^{e} W\left(T_{i}\right) \subseteq \overline{W(T)}$, and
ii. $\quad p \in \operatorname{sat}\left(T_{i}\right)$ or $p$ is regular modulo sat $\left(T_{i}\right)$, for $i=1, \ldots, e$

RegularGCD: Given $p \in \mathbf{k}[\underline{X}]$ with main variable $v, T=\left\{T_{v}\right\} \cup T_{v}^{-}$, find pairs $\left(g_{i}, T_{i}\right)$ such that:
i. $W\left(T_{v}^{-}\right) \subseteq \bigcup_{i=1}^{e} W\left(T_{i}\right) \subseteq \overline{W\left(T_{v}^{-}\right)}$, and
ii. $g_{i}$ is a regular gcd of $p, T_{v}$ w.r.t. $T_{i}$

## Finding Splittings: GCDs and Regularize

Let $p \in \mathbf{k}[\underline{X}] \backslash \mathbf{k}$ with main variable $v$. Let $T=T_{v}^{-} \cup T_{v}$. All are square free.
A regular GCD $g$ of $p$ and $T_{v}$ w.r.t. $\operatorname{sat}\left(T_{v}^{-}\right)$has:
$1 h_{g}$ is regular modulo $\operatorname{sat}\left(T_{v}^{-}\right)$
$2 g \in\left\langle p, T_{v}\right\rangle$ (every solution of $p$ and $T_{v}$ solves $g$ as well)
3 if $\operatorname{deg}(g, v)>0$, then $g$ pseudo-divides $p$ and $T_{v}$.

Let $q=\operatorname{pquo}\left(T_{v}, g\right)$. In Regularize, $g$ says where $p$ vanishes or is regular:

$$
W(T) \subseteq W\left(T_{v}^{-} \cup g\right) \cup W\left(T_{v}^{-} \cup q\right) \cup\left(V\left(h_{g}\right) \cap W(T)\right) \subseteq \overline{W(T)}
$$

In Intersect, splittings are found via recursive calls:

$$
\begin{aligned}
& V(p) \cap W(T) \subseteq \\
& \quad W\left(T_{v}^{-} \cup g\right) \cup\left(V(p) \cap\left(V\left(h_{g}\right) \cap W(T)\right)\right)
\end{aligned}
$$

$$
\subseteq V(p) \cap \overline{W(T)}
$$

## Parallel Programming Patterns

## Parallel Map, Workpile

$\rightarrow$ Map a function to each item in a collection, executing each function call simultaneously. Requires lockstep threads.
$\rightarrow$ Workpile generalizes map to a "pile" of tasks and a set of workers. Allows intermediate tasks to add more tasks, enables load-balancing

## Asynchronous Generators, Pipeline

$\rightarrow$ A generator function (a.k.a iterator, coroutine) which produces data to be consumed in parallel; special-case of producer-consumer problem
$\rightarrow$ Async generators calling other async generators create a pipeline

## Divide-and-Conquer, Fork-Join Parallelism

$\rightarrow$ Divide a problem, solve recursively, then combine sub-solutions.
$\rightarrow$ When $>1$ recursive call fork computations, perform each recursive call concurrently, then join before combining sub-solutions.

## Outline

## 1 Introduction

## 2 Preliminaries

3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Triangularize: incremental triangular decomposition

```
Algorithm 1 Triangularize \((F)\)
Input: a finite set \(F \subseteq \mathbf{k}[\underline{X}]\)
Output: regular chains \(T_{1}, \ldots, T_{e} \subseteq \mathbf{k}[\underline{X}]\) such that \(V(F)=W\left(T_{1}\right) \cup \cdots \cup W\left(T_{e}\right)\)
    1: \(\mathcal{T}:=\{\varnothing\}\)
    2: for \(p \in F\) do
3: \(\quad \mathcal{T}^{\prime}:=\{ \}\)
4: for \(T \in \mathcal{T}\) do \(\quad \triangleright\) map Intersect over the current components
5: \(\quad \mathcal{T}^{\prime}:=\mathcal{T}^{\prime} \cup \operatorname{Intersect}(p, T)\)
6: \(\quad \mathcal{T}:=\mathcal{T}^{\prime}\)
7: return RemoveRedundantComponents \((\mathcal{T})\)
```

- Coarse-grained parallelism: each Intersect represents substantial work
- At each "level" there $|\mathcal{T}|$ components with which to intersect, yielding $|\mathcal{T}|-1$ additional threads
- Performs a breadth-first search, with synchronization at each level

## Triangularize: a task-based approach

Algorithm 2 TriangularizeByTasks $(F)$
Input: a finite set $F \subseteq \mathbf{k}[\underline{X}]$
Output: regular chains $T_{1}, \ldots, T_{e} \subseteq \mathbf{k}[\underline{X}]$ such that $V(F)=W\left(T_{1}\right) \cup \cdots \cup W\left(T_{e}\right)$
1: Tasks $\leftarrow\{(F, \varnothing)\} ; \mathcal{T} \leftarrow\{ \}$
2: while $\mid$ Tasks $\mid>0$ do
3: $\quad(P, T) \leftarrow$ pop a task from Tasks
4: $\quad$ Choose a polynomial $p \in P ; P^{\prime} \leftarrow P \backslash\{p\}$
5: $\quad$ for $T^{\prime}$ in $\operatorname{Intersect}(p, T)$ do
6: $\quad$ if $\left|P^{\prime}\right|=0$ then $\mathcal{T} \leftarrow \mathcal{T} \cup\left\{T^{\prime}\right\}$
7: $\quad$ else Tasks $\leftarrow$ Tasks $\cup\left\{\left(P^{\prime}, T^{\prime}\right)\right\}$
8: return RemoveRedundantComponents $(\mathcal{T})$

- Tasks is essentially an underlying data structure for a task scheduler
- Use a thread pool of workers, each executing the body of the while loop
- Tasks create more tasks, workers pop Tasks until none remain.
- Adaptive to load-balancing, no inter-task synchronization

## Outline

## 1 Introduction

## 2 Preliminaries

## 3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

## 5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Intersect as a Generator

```
Algorithm 3 Intersect( }p,T
Input: p\in }\mathbf{k}[\underline{X}]\\mathbf{k},v:= mvar(p), a regular chain T s.t. T= T T \cup Tv
Output: regular chains }\mp@subsup{T}{1}{},\ldots,\mp@subsup{T}{e}{}\mathrm{ satisfying specs.
    1: for ( }\mp@subsup{g}{i}{},\mp@subsup{T}{i}{})\in\operatorname{RegularGCD}(p,\mp@subsup{T}{v}{},v,\mp@subsup{T}{v}{-})\mathrm{ do
2: if }\operatorname{dim}(\mp@subsup{T}{i}{})\not=\operatorname{dim}(\mp@subsup{T}{v}{-})\mathrm{ then
3: for }\mp@subsup{T}{i,j}{}\in\boldsymbol{Intersect}(p,\mp@subsup{T}{i}{})\mathrm{ do
4: yield T}\mp@subsup{T}{i,j}{
5: else
6: }\quad\mathrm{ if }\mp@subsup{g}{i}{}\not\in\mathbf{k}\mathrm{ and }\operatorname{deg}(\mp@subsup{g}{i}{},v)>0\mathrm{ then
    7: yield Ti}\mp@subsup{T}{i}{}\cup{\mp@subsup{g}{i}{}
    8: for }\mp@subsup{T}{i,j}{}\in\operatorname{Intersect(lc}(\mp@subsup{g}{i}{},v),\mp@subsup{T}{i}{})\mathrm{ do
    9: for T' }\in\boldsymbol{\operatorname{Intersect}}(p,\mp@subsup{T}{i,j}{\prime})\mathrm{ do
10: yield T'
```

$\rightarrow$ yield "produces" a single data item, and then continues computation
$\rightarrow$ each for loop consumes a data one at a time from the generator

## Generators are both Producers and Consumers

| Algorithm $3 \operatorname{Intersect}(p, T)$ |  |
| :--- | :--- |
| 1: for $\left(g_{i}, T_{i}\right) \in \operatorname{RegularGCD}\left(p, T_{v}, T_{v}^{-}\right)$do |  |
| 2: | if $\operatorname{dim}\left(T_{i}\right) \neq \operatorname{dim}\left(T_{v}^{-}\right)$then |
| 3: | for $T_{i, j} \in \operatorname{Intersect}\left(p, T_{i}\right)$ do |
| 4: | yield $T_{i, j}$ |
| 5: | else |
| 6: | if $g_{i} \notin \mathbf{k}$ and $\operatorname{deg}\left(g_{i}, v\right)>0$ then |
| 7: | yield $T_{i} \cup\left\{g_{i}\right\}$ |
| 8: | for $T_{i, j} \in \operatorname{Intersect}\left(\operatorname{lc}\left(g_{i}, v\right), T_{i}\right)$ do |
| 9: | for $T^{\prime} \in \operatorname{Intersect}\left(p, T_{i, j}\right)$ do |
| 10: | yield $T^{\prime}$ |

```
Algorithm 4 Regularize \((p, T)\)
    1: for \(\left(g_{i}, T_{i}\right) \in \operatorname{RegularGCD}\left(p, T_{v}, T_{v}^{-}\right)\)do
    2: \(\quad \triangleright\) assume \(\operatorname{dim}\left(T_{i}\right)=\operatorname{dim}\left(T_{v}^{-}\right)\)
    3: if \(0<\operatorname{deg}\left(g_{i}, v\right)<\operatorname{deg}\left(T_{v}, v\right)\) then
    4: \(\quad\) yield \(T_{i} \cup g_{i}\)
    5: \(\quad\) yield \(T_{i} \cup \operatorname{pquo}\left(T_{v}, g_{i}\right)\)
    6: \(\quad\) for \(T_{i, j} \in \operatorname{Intersect}\left(\operatorname{lc}\left(g_{i}, v\right), T_{i}\right)\) do
    7: \(\quad\) for \(T^{\prime} \in \operatorname{Regularize}\left(p, T_{i, j}\right)\) do
    8: \(\quad\) yield \(T^{\prime}\)
    9: else
    10: \(\quad\) yield \(T_{i}\)
```

$\rightarrow$ Establishing mutually recursive functions as generators allows data to stream between subroutines; subroutines are effectively non-blocking
$\rightarrow$ function call stack of generators creates a dynamic parallel pipeline.

## Subroutine Pipeline

$\rightarrow$ All subroutines as generators allows pipeline to evolve dynamically with the call stack.
$\rightarrow$ call stack forms a tree if several generators invoked by one consumer
$\rightarrow$ Pipeline creates fine-grained parallelism since work diminishes with each recursive call
$\rightarrow$ A thread pool is used and shared among all generators; generators run synchronously if pool is empty

## Outline

## 1 Introduction

## 2 Preliminaries

3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Divide-and-Conquer and Fork-Join

Remove redundancies from a list of regular chains with DnC:
$\rightarrow$ Recursively and concurrently obtain two irredundant lists, then merge.
$\rightarrow$ Cilk is used to fork/spawn and join/sync

## Algorithm 5 RemoveRedundantComponents $(\mathcal{T})$

Input: a finite set $\mathcal{T}=\left\{T_{1}, \ldots, T_{e}\right\}$ of regular chains
Output: an irredudant set $\mathcal{T}^{\prime}$ with the same algebraic set as $\mathcal{T}$
if $e=1$ then return $\mathcal{T}$
$\ell \leftarrow\lceil e / 2\rceil ; \mathcal{T}_{\leq \ell} \leftarrow\left\{T_{1}, \ldots, T_{\ell}\right\} ; \mathcal{T}_{>\ell} \leftarrow\left\{T_{\ell+1}, \ldots, T_{e}\right\}$
$\mathcal{T}_{1}:=$ spawn RemoveRedundantComponents $\left(\mathcal{T}_{\leq \ell}\right)$
$\mathcal{T}_{2}:=$ RemoveRedundantComponents $\left(\mathcal{T}_{>\ell}\right)$
sync
$\mathcal{T}_{1}^{\prime}:=\varnothing ; \quad \mathcal{T}_{2}^{\prime}:=\varnothing$
for $T_{1} \in \mathcal{T}_{1}$ do
if $\forall T_{2}$ in $\mathcal{T}_{2}$ IsNotIncluded $\left(T_{1}, T_{2}\right)$ then $\mathcal{T}_{1}^{\prime}:=\mathcal{T}_{1}^{\prime} \cup\left\{T_{1}\right\}$
for $T_{2} \in \mathcal{T}_{2}$ do
if $\forall T_{1}$ in $\mathcal{T}_{1}^{\prime}$ IsNotIncluded $\left(T_{2}, T_{1}\right)$ then $\mathcal{T}_{2}^{\prime}:=\mathcal{T}_{2}^{\prime} \cup\left\{T_{2}\right\}$
return $\mathcal{T}_{1}^{\prime} \cup \mathcal{T}_{2}^{\prime}$

## Outline

## 1 Introduction

## 2 Preliminaries

## 3 Triangularize: Task Pool Parallelization

4 Intersect: Asynchronous Generators

5 Removing Redundancies: Divide-and-Conquer

6 Experimentation

## Experimentation Setup

Thanks to Maplesoft, we have a collection of over 3000 real-world systems from: actual user data, the literature, bug reports.

Of these $>3000$ systems, 828 require greater than 0.1 s to solve
$\rightarrow$ Non-trivial systems to warrant the overheads of parallelism

203 of these 828 systems (25\%) do not split at all
$\rightarrow$ No speed-up expected; some slow-down is expected in these cases
$\rightarrow$ however, we include them to ensure that slow-down is minimal

These experiments are run on a node with $2 \times 6$-core Intel Xeon X560 processors (24 physical threads with hyperthreading)

## Speed-ups on Non-Trivial Systems (1/2)

$\rightarrow$ "Coarse": task manager only, "Fine": tasks and generators
$\rightarrow$ Adding generators increases parallelism: streaming components allows Triangularize to create a new task as early as possible

## Speed-ups on Non-Trivial Systems $(2 / 2)$

$\rightarrow$ "Coarse": task manager only, "Fine": tasks and generators
$\rightarrow$ Adding generators increases parallelism: streaming components allows Triangularize to create a new task as early as possible

## Inspecting the Geometry: Sys2691

Sys2691 Component Tree

$\rightarrow$ Bottom "main" branch is majority of the work.
$\rightarrow$ Little overlap with the quickly-solved degenerative branches
$\rightarrow 2.13 \times$ speedup achieved; $88 \%$ efficient compared to work/span ratio

## Conclusion \& Future Work

We have tackled irregular parallelism in a high-level algebraic algorithm
$\rightarrow$ our solution dynamically finds and exploits possible parallelism
$\rightarrow$ uses dynamic parallel task management, async. generators, and DnC
Further parallelism can be found through:
$\rightarrow$ evaluation/interpolation schemes for subresultant chains
$\rightarrow$ solving over a prime field produces more splittings; then lift solutions
Our parallel techniques could be employed in further high-level algorithms.
$\rightarrow$ e.g. factorization: pipelining between square-free, distinct-degree, and equal-degree factorization

## Thank You!

I look forward to your questions:
$\rightarrow$ during the live $Q / A$ session,
$\rightarrow$ at a Zoom Meeting 18:00-19:00 EEST July 21 2020: https://westernuniversity.zoom.us/j/93900888047 (Meeting ID: 93900888047)
