Triangular decompositions over the rationals with finitely many solutions can be computed as follows:

1. Solve modulo a “small” prime $p_1$ and use Hensel lifting to recover a triangular decomposition over the rationals.

2. Use another “small” prime $p_2$ to check whether the lifted decomposition reduced modulo $p_2$ matches the decomposition computed modulo $p_2$.

3. If success then returns the lifted decomposition otherwise go back to Step 1.

For large input systems, it is desirable to use larger primes, possibly of size several machine words, so as to increase success in one loop iteration.

Contributions and main results

- Algorithms and CUDA implementation for arithmetic operations in $\mathbb{Z}/p\mathbb{Z}$, where $p$ is Generalized Fermat prime of size 8 or 16 machine words.
- CUDA implementation of FFT over such big prime field $\mathbb{Z}/p\mathbb{Z}$
- Theoretical and practical comparison of this big prime field FFT vs. an approach based on small prime fields and CRT.

Discrete Fourier transform

Definition

Let \( \mathcal{R} \) be a commutative ring with unity and \( \omega \in \mathcal{R} \) be a principal \( N \)-th root of unity. The linear map \( \vec{a} = (a_0, \ldots, a_{N-1})^T \xrightarrow{\Omega} \vec{b} = (b_0, \ldots, b_{N-1})^T \) with matrix \( \Omega = (\omega^{jk})_{0 \leq j, k \leq N-1} \) is the DFT \( N \) at \( \omega \).

Cooley-Tukey factorization formula

- For \( J, K > 1 \), we have:

\[
\text{DFT}_{JK} = (\text{DFT}_J \otimes I_K)D_{J,K}(I_J \otimes \text{DFT}_K)L_{JK}^J
\]

where

\[
D_{J,K} = \bigoplus_{j=0}^{J-1} \text{diag}(1, \omega^j, \ldots, \omega^{j(K-1)})
\]

\[
L_{JK}^J = x[iJ + j] \mapsto x[jJ + i], (0 \leq j < J, 0 \leq i < K).
\]

- Various fast Fourier transform (FFT) algorithms can be derived from this formula, including Cooley-Tukey (CT) and Stockham.
FFT over a prime field

- Let \( p \) be a prime and \( N \) be a power of 2 s.t. \( N \mid p - 1 \).
- Then, \( \mathbb{Z}/p\mathbb{Z} \) admits a \( N \)-th primitive root of unity, say \( \omega \).
- Let \( f \in \mathbb{Z}/p\mathbb{Z}[x] \) be a polynomial of degree at most \( N - 1 \).
- Computing \( \text{DFT}_N(f) \) at \( \omega \) by a FFT amounts to
  - \( N \log(N) \) additions in \( \mathbb{Z}/p\mathbb{Z} \),
  - \( N/2 \log(N) \) multiplications by a power of \( \omega \) in \( \mathbb{Z}/p\mathbb{Z} \),
- If \( p \) spans \( k \) machine words, then each addition costs \( O(k) \) word ops., and each multiplication by a power of \( \omega \) costs \( O(M(k)) \) word ops.
- Here, \( n \mapsto M(n) \) is a multiplication time.
- Hence, multiplication by a power of \( \omega \) becomes a bottleneck as \( k \) grows.

Complexity analysis

Fürer’s trick

- Let \( N = K^e \) for some “small” \( K \) (say \( K = 32 \)) and an integer \( e \geq 2 \).
- Define \( \eta = \omega^{N/K} \), let \( J = K^{e-1} \), and assume that multiplying an arbitrary element of \( \mathbb{Z}/p\mathbb{Z} \) by \( \eta^i \) \((0 \leq i \leq K)\) can be done within \( O(k) \) word ops.
- Every arithmetic operation involved in \( \text{DFT}_K \) at \( \eta \) costs \( O(k) \) word ops.
- Therefore, such \( \text{DFT}_K \) can be performed within \( O(K \log(K)k) \) word ops.
- This latter result holds whenever \( p \) is a generalized Fermat number.

Recall the CT factorization:

\[
\text{DFT}_{JK} = (\text{DFT}_J \otimes I_K)D_{J,K}(I_J \otimes \text{DFT}_K)L_{JK}^J,
\]

(1)

the DFT of \( f \) at \( \omega \) is essentially performed by:

- \( J = K^{e-1} \) DFT’s of size \( K \),
- \( N \) multiplication by a power of \( \omega \) (coming from the diagonal matrix \( D_{J,K} \))
- \( K \) DFT’s of size \( J = K^{e-1} \).
Applying Furer’s trick to CT factorization

Unrolling Formula (1) (replace $DFT_J$ by $DFT_K$) yields:

- $e K^{e-1} \ DFT_K$’s (each at cost $O(K \log_2(K) k)$ word ops.),
  in total $O(e N \log_2(K) k)$ word ops.,

- $(e - 1) N$ multiplication by a power of $\omega$ (each at cost $O(M(k))$ word ops.),
  in total $O(e N M(k)) = O(N \log_K(N) M(k))$ word ops.

So, $DFT_N(\omega)$ amounts to $O(N \log_2(N) k + N \log_K(N) M(k))$ word ops.

Using generalized Fermat primes, we have $K = 2^k$, therefore:

$$O(N \log_2(N) k + N \log_k(N) M(k))$$

(2) dominant term

- Without our assumption, the same DFT would run in $O(N \log_2(N) M(k))$ word ops.

- Therefore, using generalized Fermat primes brings a speedup factor of $\log(K)$ w.r.t. the direct approach using arbitrary prime numbers.
The cost of a comparable computation using small primes and the CRT

- Let \( p_1, \ldots, p_k \) be pairwise different prime numbers of machine-word size and let \( m \) be their product.

- Assume that \( N \) divides each of \( p_1 - 1, \ldots, p_k - 1 \) such that each of fields \( \mathbb{Z}/p_1\mathbb{Z}, \ldots, \mathbb{Z}/p_k\mathbb{Z} \) admits an \( N \)-th primitive roots of unity, \( \omega_1, \ldots, \omega_k \).

- Then, \( \omega = (\omega_1, \ldots, \omega_k) \) is an \( N \)-th primitive root of \( \mathbb{Z}/m\mathbb{Z} \). Indeed, the ring \( \mathbb{Z}/p_1\mathbb{Z} \otimes \cdots \otimes \mathbb{Z}/p_k\mathbb{Z} \) is a direct product of fields isomorphic to \( \mathbb{Z}/m\mathbb{Z} \).

- Let \( f \in \mathbb{Z}/m\mathbb{Z}[x] \) be a polynomial of degree \( N - 1 \).
One can compute the DFT of $f$ at $\omega$ in three steps:

1. Compute the images $f_1 \in \mathbb{Z}/p_1\mathbb{Z}[x], \ldots, f_k \in \mathbb{Z}/p_k\mathbb{Z}[x]$ of $f$.
2. Compute the DFT of $f_i$ at $\omega_i$ in $\mathbb{Z}/p_i\mathbb{Z}[x]$, for $i = 1, \ldots, k$.
3. Combine the results using CRT so as to obtain a DFT of $f$ at $\omega$.

The 1st and the 3rd steps will run within $O(N \times M(k) \log_2(k))$ word ops.

The 2nd step amounts to $O(k \times N \log(N))$ word ops.

In total:

$$O(N \log_2(N) k + N M(k) \log_2(k))$$  \hspace{1cm} (3)$$

These estimates yield a running-time ratio between the two approaches of $\log(N)/\log_2(k)$, which suggests that for $k$ large enough the big prime field approach may outperform the CRT-based approach.

This analysis is part of the explanation for the observation that the two approaches are, competitive in practice, as we shall see in experimental results.

Sparse-radix generalized Fermat numbers (SRGFN)

- Generalized Fermat numbers $a^{2^n} + b^{2^n}$ where $a > 1$, $b \geq 0$ and $n \geq 0$.
- For $F_n(a) = a^{2^n} + 1$, $a$ is a $2^{n+1}$-th primitive root of unity $\mathbb{Z}/F_n(a)\mathbb{Z}$.
- A SRGFN is any $F_n(r)$ where $r$ is $2^w + 2^u$ or $2^w - 2^u$, for $w > u \geq 0$.

Representing elements of $\mathbb{Z}/F_n(r)\mathbb{Z}$

- Let $p = F_n(r)$, and $k = 2^n$ s.t. $p = r^k + 1$ holds.
- Represent $x \in \mathbb{Z}/p\mathbb{Z}$ as $\vec{x} = (x_{k-1}, x_{k-2}, \ldots, x_0)$ such that:

  $$x \equiv x_{k-1} r^{k-1} + x_{k-2} r^{k-2} + \cdots + x_0 \mod p.$$ 

  1. either $x_{k-1} = r$ and $x_{k-2} = \cdots = x_1 = 0$, or
  2. $0 \leq x_i < r$ for all $i = 0 \cdots (k - 1)$
Addition and subtraction in $\mathbb{Z}/p\mathbb{Z}$

- $x, y \in \mathbb{Z}/p\mathbb{Z}$ represented by vectors $\vec{x}, \vec{y}$ with $k$ coefficients

Multiplication in $\mathbb{Z}/p\mathbb{Z}$

- Associate $x, y \in \mathbb{Z}/p\mathbb{Z}$ with polynomials $f_x, f_y \in \mathbb{Z}[T]$ 

- For large $k$, $f_x f_y \mod T^k + 1$ can be computed in $\mathbb{Z}[T]$ by fast algorithms

- For small $k$, say $k \leq 16$, using plain multiplication is reasonable.

Multiplication by $r^i$ for some $0 < i < 2k$ in $\mathbb{Z}/p\mathbb{Z}$

- Recall that $r^{2k} \equiv 1$, $r^k \equiv -1$, and $r^{k+i} \equiv -r^i$, for $0 < i < k$

- Assume that $0 < i < k$ holds and $0 \leq x < r^k$ holds in $\mathbb{Z}$, then:

  \[
  x \cdot r^i \equiv x_{k-1} r^{k-1+i} + \cdots + x_0 r^i \mod p
  \]

  \[
  \equiv \sum_{j=0}^{j=k-1} x_j r^{j+i} \mod p \equiv \sum_{h=i}^{h=k-1+i} x_{h-i} r^h \mod p
  \]

  \[
  \equiv \sum_{h=i}^{h=k-1} x_{h-i} r^h - \sum_{h=k}^{h=k-1+i} x_{h-i} r^{h-k} \mod p
  \]

- Computing the product $x \cdot r^i$ reduces to a negacyclic shift.

6 Implementation

7 Experimental Comparison
We use NVIDIA CUDA, a platform for writing scalable parallel programs on GPUs.

Our code is tuned for SRGFN’s $P_3 := (2^{63} + 2^{34})^8 + 1$ and $P_4 := (2^{62} + 2^{36})^{16} + 1$.

**Choice of algorithm:**

- **Block parallelism** can be realized by $I_J \otimes \text{DFT}_K$.

- The CT algorithm cannot exploit block parallelism on GPUs!

- Instead, we use the **six-step recursive FFT algorithm**

\[
\text{DFT}_N = L_K^N(I_J \otimes \text{DFT}_K)L_J^N D_{K,J}(I_K \otimes \text{DFT}_J)L_K^N.
\]

- We expand $I_K \otimes \text{DFT}_J$ to turn all DFT computations to base-case $\text{DFT}_K$. 
Parallelization.

In our implementation, each arithmetic operation is computed by one thread.

Memory-bound kernels.

- Performance is limited by frequent accesses to memory.
- We have considered solutions for:
  - minimizing memory latency,
  - maximizing occupancy (no. of active warps on each streaming multiprocessor) to hide latency, and
  - maximizing IPC (instructions per clock cycle).
- Location of data: keep all data on global memory!

Decomposing computation into multiple kernels.

- Using too many registers per thread can lower the occupancy, or can even lead to register spilling.
- Solution: register-intensive kernels are broken into multiple smaller ones.
Implementation notes (3)

Size of thread blocks.

- Kernels do not depend on the size of a thread block.
- We choose size of thread blocks for maximizing:
  - the occupancy,
  - the IPC (instruction per clock cycle), and
  - bandwidth-related performance metrics (read and write throughput).

Effect of GPU instructions on performance.

- Current implementation relies on 64-bit instructions (due to 64-bit radix).
- NVIDIA GPUs support 64-bit integer instructions, however, compiler converts all instructions to a sequence of 32-bit equivalents.
- This conversion might have a negative impact on the overall performance (specially, 64-bit multiplication!).
- Finally, using 32-bit arithmetic provides more opportunities for optimization, e.g. instruction level parallelism.
Maximizing global memory efficiency.

- Assume that for a vector of $\vec{X}$ of $N$ elements of $\mathbb{Z}/p\mathbb{Z}$, consecutive digits of each element are stored in adjacent memory addresses.

- Such a vector can be considered as the row-major layout of a $N \times k$ matrix.

- In practice, this data structure will hurt performance due to increased memory overhead, caused by non-coalesced accesses to global memory.

- An effective solution is to perform a stride permutation $L_{kN}^k$ on all input vectors.

- Therefore, accesses to global memory will be coalesced, increasing memory load and store efficiency, and lowering the memory overhead.

\[
M_0 = \begin{bmatrix}
\vec{X}_0 \\
\vec{X}_1 \\
\vdots \\
\vec{X}_{N-1}
\end{bmatrix}
= \begin{bmatrix}
\vec{X}_{(0,0)} & \cdots & \vec{X}_{(0,k-1)} \\
\vec{X}_{(1,0)} & \cdots & \vec{X}_{(1,k-1)} \\
\vdots & \ddots & \vdots \\
\vec{X}_{(N-1,0)} & \cdots & \vec{X}_{(N-1,k-1)}
\end{bmatrix}_{(N \times k)}
\xrightarrow{L_{kN}^k}
\begin{bmatrix}
\vec{X}_{(0,0)} \\
\vec{X}_{(0,1)} \\
\vdots \\
\vec{X}_{(0,k-1)} \\
\vec{X}_{(N-1,0)} \\
\vec{X}_{(N-1,1)} \\
\vdots \\
\vec{X}_{(N-1,k-1)}
\end{bmatrix}_{(k \times N)}
\]

Computing FFT: big prime vs. small prime

- Small prime approach: pairwise different primes \( p_1, \ldots, p_k \)
  
  1. compute image \( f_i \) of \( f \) in \( \mathbb{Z}/p_1\mathbb{Z}[x], \ldots, \mathbb{Z}/p_k\mathbb{Z}[x] \) (projection)
  2. compute \( \text{DFT}_N(f_i) \) at \( \omega_i \) in \( \mathbb{Z}/p_i\mathbb{Z}[x] \)
  3. combine the results using the CRT (recombination)

- The small primes are \( \frac{\text{machine-word size}}{2} \), it is fair to use \( 2^k \) of them!

- For comparing against \( P_3 = (2^{63} + 2^{34})^8 + 1 \) and \( P_4 = (2^{62} + 2^{36})^{16} + 1 \) we pick 16 and 32 small primes, respectively.

- Small prime FFTs from the CUMODP library compute \( \text{DFT}_{2^n} \) for \( 8 \leq n \leq 26 \):
  - the Cooley-Tukey FFT,
  - the Cooley-Tukey FFT with pre-computed powers of \( \omega \),
  - the Stockham FFT.

- Tests completed on a NVIDIA GeforceGTX760M card
Benchmarking for $P_3 = (2^{63} + 2^{34})^8$ ($K = 16$)

Performance analysis:

- The CUMODP FFTs are fast for $N \geq 2^{16}$ (high occupancy)
- Larger $p$ in $\mathbb{Z}/p\mathbb{Z}$ $\Rightarrow$ a higher number of cheap multiplications
- For $p = r^8 + 1$ and $K = 2^k = 16$, the best results for DFT$_{N=K^4}$
- Beyond that point, we have more expensive multiplications!
Benchmarking for $P_4 = (2^{62} + 2^{36})^{16} (K = 32)$

![Bar chart showing speedup for CT-pre, CT, and Stockholm for different $K$ values.]

- $K^2$: 49.34, 25.15, 33.06
- $K^3$: 3.08, 1.94, 2.29
- $K^4$: 1.82, 1, 1.07

Concluding remarks

Conclusions

- Big prime field arithmetic is required by advanced algorithms in computer algebra (like polynomial system solving).
- Arithmetic modulo a big prime can be efficiently computed on GPUs.
- Transposing input data increases memory usage efficiency.
- Computing FFT in $\mathbb{Z}/p\mathbb{Z}$ is competitive with a CRT-based approach for a range of sizes.
- Nevertheless, multiplication in $\mathbb{Z}/p\mathbb{Z}$ (except for the case of a multiplication by a power of $r$) remains a computational bottleneck.

Work in progress

- Improving multiplication in $\mathbb{Z}/p\mathbb{Z}$ is work in progress.
- By choosing a larger prime, say with $k = 32$ instead of $k = 8$, or $k = 16$, we hope to cover other ranges of sizes.

Finding primitive roots of unity in $\mathbb{Z}/p\mathbb{Z}$

Computing $\omega$:

- **Goal**: speed up $x\omega^i$ for $x \in \mathbb{Z}/p\mathbb{Z}$.
- Let $N = 2^\ell$, s.t. $N \mid p - 1$
- Assume that $g^N = 1$ for $g \in \mathbb{Z}/p\mathbb{Z}$
- Write $p = qN + 1$.
- Pick a random $\alpha \in \mathbb{Z}/p\mathbb{Z}$
- Let $\omega = \alpha^q$.

Fermat’s little theorem:
- if $\omega^{N/2} = 1 \Rightarrow \omega^N = 1$,
- if $\omega^{N/2} = -1$, pick another $\alpha$.

---

Algorithm 1 Primitive $N$-th root $\omega \in \mathbb{Z}/p\mathbb{Z}$ s.t. $\omega^{N/2^k} = r$

```
procedure PRoot($N, r, k, g$)
    $\alpha := g^{N/2^k}$
    $\beta := \alpha$
    $j := 1$
    while $\beta \neq r$ do
        $\beta := \alpha \beta$
        $j := j + 1$
    end while
    $\omega := g^j$
    return $(\omega)$
end procedure
```

\end{bmatrix}
Mixed-radix conversion

Mixed-radix representation

- For pairwise different primes $p_1, \ldots, p_s$:

  $$ b_i \in \mathbb{Z}/p_i\mathbb{Z}, \quad 0 \leq b_i < p_i, \quad (1 \leq i \leq s). $$

- Then $(b_1, b_2, \ldots, b_s)$ is mixed-radix representation of $n \in \mathbb{Z}$:

  \[
  \left\{
  \begin{array}{l}
  n = b_1 + b_2p_1 + b_3p_1p_2 + \cdots + b_sp_1\cdots p_{s-1} \\
  0 \leq n < p_1p_2\cdots p_s
  \end{array}
  \right.
  \]

Reconstructing $n$ from $(b_1, b_2, \ldots, b_s)$

- pre-compute $m_1 := p_1$, $m_2 := p_1p_2$, $\ldots$, $m_s := m$,

- compute $u_i := b_im_i$ (stored in $i$ machine-words),

- compute the sum $n := u_1 + u_2 + \ldots + u_s$
Recombination step

MRR or CRT?

- The CRT defines a ring isomorphism:

\[ \mathbb{Z}/p_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/p_s\mathbb{Z} \cong \mathbb{Z}/(p_1 \times \ldots \times p_s)\mathbb{Z} \]

- The MRR defines a bijection:

\[ \mathbb{Z}/p_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/p_s\mathbb{Z} \mapsto [0, p_1 p_2 \cdots p_s] \]

which preserves the order (mapping lex-order to <)

- Both take \( \Theta(k^2) \) machine-word operations.
- The MRR is interesting for modular methods for real numbers
- We use MRR map instead of the CRT.
Computing equivalent results

- Compute a $\text{DFT}_N$ in $\mathbb{Z}/p\mathbb{Z}$ with $p = r^k + 1 \rightarrow \mathcal{O}(N \log_K(N)k^2)$
- Compute $s$ $\text{DFT}_N$ over small prime fields. $\rightarrow \mathcal{O}(sN \log_2(N))$
- Compute a MRR on results of small prime FFTs $\rightarrow \mathcal{O}(sNk^2)$
• Expanding $\text{DFT}_{16}$ based on the six-step FFT algorithm:

$$\text{DFT}_{16} = L_2^{16}(l_8 \otimes \text{DFT}_2)L_8^{16}D_{2,8}^{16}(l_2 \otimes \text{DFT}_8)L_2^{16},$$

$$\text{DFT}_8 = L_2^8(l_4 \otimes \text{DFT}_2)L_4^8D_{2,4}^8(l_2 \otimes \text{DFT}_4)L_2^8,$$

$$\text{DFT}_4 = L_2^4(l_2 \otimes \text{DFT}_2)L_2^4D_{2,2}^4(l_2 \otimes \text{DFT}_2)L_2^4,$$

• Following multiplications by twiddle factors are required:

1. $\text{DFT}_{16}$ with $\omega_0 = \omega^{N/K} = r$,
2. $\text{DFT}_8$ needs $\omega_1 = \omega^{(N/K)^2} = r^2$,
3. $\text{DFT}_4$ needs $\omega_2 = \omega^{(N/K)^4} = r^4$.

• We have:

$$D_{2,8}^{16} = (1, 1, 1, 1, 1, 1, 1, r^0, r^1, r^2, r^3, r^4, r^5, r^6, r^7),$$

$$D_{2,4}^8 = (1, 1, 1, 1, r^0, r^2, r^4, r^6),$$

$$D_{2,2}^4 = (1, 1, r^0, r^4).$$
Addition and subtraction in \( \mathbb{Z}/p\mathbb{Z} \)

- \( x, y \in \mathbb{Z}/p\mathbb{Z} \) represented by \( \vec{x}, \vec{y} \)

**Algorithm 6** Computing \( x + y \in \mathbb{Z}/p\mathbb{Z} \) for \( x, y \in \mathbb{Z}/p\mathbb{Z} \)

**procedure** BigPrimeFieldAddition(\( \vec{x}, \vec{y}, r, k \))

1: compute \( z_i = x_i + y_i \) in \( \mathbb{Z} \), for \( i = 0, \ldots, k - 1 \),
2: let \( z_k = 0 \),
3: for \( i = 0, \ldots, k - 1 \), compute the quotient \( q_i \) and the remainder \( s_i \) in the Euclidean division of \( z_i \) by \( r \), then replace \((z_{i+1}, z_i)\) by \((z_{i+1} + q_i, s_i)\),
4: if \( z_k = 0 \) then return \((z_{k-1}, \ldots, z_0)\),
5: if \( z_k = 1 \) and \( z_{k-1} = \cdots = z_0 = 0 \), then let \( z_{k-1} = r \) and return \((z_{k-1}, \ldots, z_0)\),
6: let \( i_0 \) be the smallest index, \( 0 \leq i_0 \leq k \), such that \( z_{i_0} \neq 0 \), then let \( z_{i_0} = z_{i_0} - 1 \), let \( z_0 = \cdots = z_{i_0-1} = r - 1 \) and return \((z_{k-1}, \ldots, z_0)\).

**end procedure**
Multiplication in $\mathbb{Z}/p\mathbb{Z}$

- Associate $x, y \in \mathbb{Z}/p\mathbb{Z}$ $\longrightarrow f_x, f_y \in \mathbb{Z}[T]$
- For large $k$, can compute $f_x f_y \mod T^k + 1$ in $\mathbb{Z}[T]$ by fast algorithms
- For small $k$, say $k \leq 8$, using plain multiplication is reasonable.

**Algorithm 7** Computing $xy \in \mathbb{Z}/p\mathbb{Z}$ for $x, y \in \mathbb{Z}/p\mathbb{Z}$

```plaintext
procedure BigPrimeFieldMultiplication($f_x, f_y, r, k$)

1: We compute the polynomial product $f_u = f_x f_y$ in $\mathbb{Z}[T]$ modulo $T^k + 1$.

2: Writing $f_u = \sum_{i=0}^{k-1} u_i T^i$, we observe that for all $0 \leq i \leq k - 1$ we have $0 \leq u_i \leq kr^2$ and compute a representation $\overrightarrow{u_i}$ of $u_i$ in $\mathbb{Z}/p\mathbb{Z}$ explained in Section ??.

3: We compute $u_i r^i$ in $\mathbb{Z}/p\mathbb{Z}$ using the method of Section ??.

4: Finally, we compute the sum $\sum_{i=0}^{k-1} u_i r^i$ in $\mathbb{Z}/p\mathbb{Z}$ using Algorithm 6.

end procedure
```
