A multi-core processor is an integrated circuit to which two or more individual processors (called cores in this sense) have been attached.

In a many-core processor the number of cores is large enough that traditional multi-processor techniques are no longer efficient.

Cores on a multi-core device can be coupled tightly or loosely:
- may share or may not share a cache,
- implement inter-core communications methods or message passing.

Cores on a multi-core implement the same architecture features as single-core systems such as instruction pipeline parallelism (ILP), vector-processing, SIMD or multi-threading.

Many applications do not realize yet large speedup factors: parallelizing algorithms and software is a major on-going research area.
Multi-core Architecture
CPU Coherence

Cache Coherence (1/6)

**Figure:** Processor $P_1$ reads $x=3$ first from the backing store (higher-level memory)

Cache Coherence (2/6)

**Figure:** Next, Processor $P_2$ loads $x=3$ from the same memory

Cache Coherence (3/6)

**Figure:** Processor $P_4$ loads $x=3$ from the same memory

Cache Coherence (4/6)

**Figure:** Processor $P_2$ issues a write $x=5$
In this cache coherence protocol each block contained inside a cache can have one of three possible states:

- **M**: the cache line has been **modified** and the corresponding data is inconsistent with the backing store; the cache has the responsibility to write the block to the backing store when it is evicted.
- **S**: this block is unmodified and is **shared**, that is, exists in at least one cache. The cache can evict the data without writing it to the backing store.
- **I**: this block is **invalid**, and must be fetched from memory or another cache if the block is to be stored in this cache.

These coherency states are maintained through communication between the caches and the backing store.

The caches have different responsibilities when blocks are read or written, or when they learn of other caches issuing reads or writes for a block.

**True sharing**: True sharing cache misses occur whenever two processors access the same data word. True sharing requires the processors involved to explicitly synchronize with each other to ensure program correctness. A computation is said to have **temporal locality** if it re-uses much of the data it has been accessing. Programs with high temporal locality tend to have less true sharing.

**False sharing**: False sharing results when different processors use different data that happen to be co-located on the same cache line. A computation is said to have **spatial locality** if it uses multiple words in a cache line before the line is displaced from the cache. Enhancing spatial locality often minimizes false sharing.

See *Data and Computation Transformations for Multiprocessors* by J.M. Anderson, S.P. Amarasinghe and M.S. Lam:

http://suif.stanford.edu/papers/anderson95/paper.html
Multi-core processor (cntd)

**Advantages:**
- Cache coherency circuitry operate at higher rate than off-chip.
- Reduced power consumption for a dual core vs two coupled single-core processors (better quality communication signals, cache can be shared)

**Challenges:**
- Adjustments to existing software (including OS) are required to maximize performance
- Production yields down (an Intel quad-core is in fact a double dual-core)
- Two processing cores sharing the same bus and memory bandwidth may limit performances
- High levels of false or true sharing and synchronization can easily overwhelm the advantage of parallelism

Concurrency Platforms

**Concurrency Platforms**

**An overview of Cilk++**

Cilk++ (resp. Cilk) is a small set of linguistic extensions to C++ (resp. C) supporting fork-join parallelism

Both Cilk and Cilk++ feature a provably efficient work-stealing scheduler.

Cilk++ provides a hyperobject library for parallelizing code with global variables and performing reduction for data aggregation.

Cilk++ includes the Cilkscreen race detector and the Cilkview performance analyzer.

From Cilk to Cilk++

Cilk has been developed since 1994 at the MIT Laboratory for Computer Science by Prof. Charles E. Leiserson and his group, in particular by Matteo Frigo.

Besides being used for research and teaching, Cilk was the system used to code the three world-class chess programs: Tech, Socrates, and Cilkchess.

Over the years, the implementations of Cilk have run on computers ranging from networks of Linux laptops to an 1824-nodes Intel Paragon.

From 2007 to 2009 Cilk has lead to Cilk++, developed by Cilk Arts, an MIT spin-off, which was acquired by Intel in July 2009 and became Cilk Plus, see http://www.cilk.com/

Cilk is still developed at MIT http://supertech.csail.mit.edu/cilk/
Nested Parallelism in Cilk++

int fib(int n) {
    if (n < 2) return n;
    int x, y;
    x = cilk_spawn fib(n-1);
    y = fib(n-2);
    cilk_sync;
    return x+y;
}

- The named child function cilk_spawn fib(n-1) may execute in parallel with its parent executes fib(n-2).
- Cilk++ keywords cilk_spawn and cilk_sync grant permissions for parallel execution. They do not command parallel execution.

Serial Semantics (1/2)

- Cilk (resp. Cilk++) is a multithreaded language for parallel programming that generalizes the semantics of C (resp. C++) by introducing linguistic constructs for parallel control.
- Cilk (resp. Cilk++) is a faithful extension of C (resp. C++):
  - The C (resp. C++) elision of a Cilk (resp. Cilk++) is a correct implementation of the semantics of the program.
  - Moreover, on one processor, a parallel Cilk (resp. Cilk++) program scales down to run nearly as fast as its C (resp. C++) elision.
- To obtain the serialization of a Cilk++ program
  #define cilk_for for
  #define cilk_spawn
  #define cilk_sync

Serial Semantics (2/2)

The iterations of a cilk_for loop may execute in parallel.

int fib (int n) {
if (n<2) return (n);
else {
int x,y;
x =  cilk spawn fib(n-1);
y = fib(n-2);
cilk_sync;
return (x+y);
}
} Serialization

Cilk++ source

int fib (int n) {
if (n<2) return (n);
else {
int x,y;
x = cilk_spawn fib(n-1);
y = fib(n-2);
cilk_sync;
return (x+y);
}
}
Scheduling

```c
int fib (int n) {
    if (n<2) return (n); else {
        int x, y;
        x = cilk_spawn fib(n-1);
        y = fib(n-2);
        cilk_sync;
        return (x+y);
    }
}
```

Race Bugs (1/3)

- Iterations of a `cilk_for` should be independent.
- Between a `cilk_spawn` and the corresponding `cilk_sync`, the code of the spawned child should be independent of the code of the parent, including code executed by additional spawned or called children.
- The arguments to a spawned function are evaluated in the parent before the spawn occurs.

Race Bugs (2/3)

```c
int x = 0;
1
x = 0;
1
2
r1 = x;
3
r1++;
4
r2 = x;
5
r2++;
7
x = r1;
6
x = r2;
8
assert(x == 2);
```

- Watch out for races in packed data structures such as:
  ```
  struct{
      char a;
      char b;
  }
  ```
  Updating `x.a` and `x.b` in parallel can cause races.
- If an ostensibly deterministic Cilk++ program run on a given input could possibly behave any differently than its serialization, Cilkscreen race detector guarantees to report and localize the offending race.
  ```
  Employs a regression-test methodology (where the programmer provides test inputs) and dynamic instrumentation of binary code.
  ```
  Identifies files-names, lines and variables involved in the race.
- Runs about 20 times slower than real-time.
template<typename T> void multiply_iter_par(int ii, int jj, int kk, T* A, T* B, T* C) {
    cilk_for(int i = 0; i < ii; ++i)
        for (int k = 0; k < kk; ++k)
            cilk_for(int j = 0; j < jj; ++j)
                C[i * jj + j] += A[i * kk + k] + B[k * jj + j];
}

Does not scale up well due to a poor locality and uncontrolled granularity.

template<typename T> inline void multiply_rec_seq_helper(int i0, int i1, int j0, int j1, int k0, int k1, T* A, ptrdiff_t lda, T* B, ptrdiff_t ldb, T* C, ptrdiff_t ldc) {
    int di = i1 - i0;
    int dj = j1 - j0;
    int dk = k1 - k0;
    if (di >= dj && di >= dk && di >= RECURSION_THRESHOLD) {
        int mi = i0 + di / 2;
        multiply_rec_seq_helper(i0, mi, j0, j1, k0, k1, A, lda, B, ldb, C, ldc);
        multiply_rec_seq_helper(mi, i1, j0, j1, k0, k1, A, lda, B, ldb, C, ldc);
    } else if (dj >= dk && dj >= RECURSION_THRESHOLD) {
        int mj = j0 + dj / 2;
        multiply_rec_seq_helper(i0, i1, mj, j0, j1, k0, k1, A, lda, B, ldb, C, ldc);
        multiply_rec_seq_helper(i0, i1, mj, j1, k0, k1, A, lda, B, ldb, C, ldc);
    } else if (dk >= RECURSION_THRESHOLD) {
        int mk = k0 + dk / 2;
        multiply_rec_seq_helper(i0, i1, j0, j1, mk, k0, k1, A, lda, B, ldb, C, ldc);
        multiply_rec_seq_helper(i0, i1, j0, j1, mk, k1, A, lda, B, ldb, C, ldc);
    } else {
        for (int i = i0; i < i1; ++i)
            for (int k = k0; k < k1; ++k)
                for (int j = j0; j < j1; ++j)
                    C[i * ldc + j] += A[i * lda + k] * B[k * ldb + j];
    }
}

Multiplying a 4000x8000 matrix by a 8000x4000 matrix
- on 32 cores = 8 sockets x 4 cores (Quad Core AMD Opteron 8354) per socket.
- The 32 cores share a L3 32-way set-associative cache of 2 Mbytes.
