# CS 2033

## Multimedia & Communications II

LECTURE 5 – CASCADING STYLE SHEETS (CSS)

2

## Announcements

- ▶ Quiz 1 is this Wednesday-Thursday.
  - ▶ You may look at the lecture slides and your notes.
  - ▶ It will have some think-outside-the-box questions.
- ▶ Assignment 2 will be coming out later this week.

3

## CSS

- ▶ Cascading Style Sheets
- ▶ CSS is used only to style websites.
- ▶ This is the standard for styling and goes hand in hand with HTML.
- ▶ Used for layouts/positioning of elements and their appearance, like colour, font colour, border, etc.

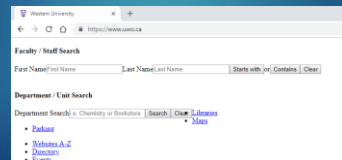

4

## CSS

With CSS

Without CSS

## CSS

- ▶ Remember that divs and many other HTML elements can be nested within one another.
- ▶ This is helpful for creating layouts.
- ▶ This relationship is known as parent-child, where the parent is the container / outer element and the child is the inner element.

6

## CSS

- ▶ What styles can be applied in CSS?
  - ▶ Tons! You'll need to know the common ones but not all of them.
- ▶ How are they applied?
  - ▶ 3 main ways to apply the basic styles (more for advanced styles).
- ▶ Where does CSS code go?
  - ▶ 3 different placement options.

## Style types

7

- ▶ Layout
  - ▶ Width, height
  - ▶ Position type
  - ▶ Position values
  - ▶ Display type / float
  - ▶ Margins and padding
  - ▶ Top, right, bottom, and left (I call these TRBL or "trouble" ☺)

## Style types

8

- ▶ Appearance
  - ▶ Background colour
  - ▶ Background image/texture
  - ▶ Font colour
  - ▶ Border style
  - ▶ Rounded corners
  - ▶ Opacity

## Style types

9

- ▶ Many styles overlap both categories but I try to categorize them by their primary function.
  - ▶ i.e. size is used for layout but also impacts the appearance.
- ▶ Some styles only work if other styles are set in a certain way.
  - ▶ You will see this very soon when we discuss positioning.

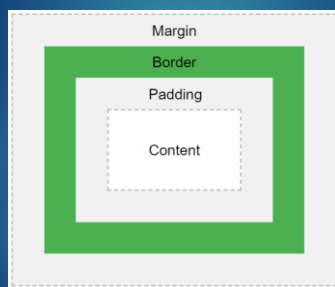

## Layout-based styles

10

- ▶ **Width** and **height** are simple.
- ▶ **Padding** is the space just inside the element, keeping its contents away from the edge.
- ▶ **Margin** is the space outside the element, keeping it away from other elements.
- ▶ Most size styles are in px or %.

## Layout-based styles

11

## Layout-based styles

12

- ▶ Positioning elements can be done a few ways (or a combination).
- ▶ By default, elements are added sequentially top to bottom.
- ▶ Depending on size and layout styles, they may be added left to right in a row too.

## Layout-based styles

13

- ▶ The **position** style type determines how (but not where!) the element is positioned in the page or its parent.
- ▶ The default value is static, meaning it's added sequentially in the site and cannot be moved.

## Layout-based styles

14

- ▶ Other **position** options are:
  - ▶ Relative – similar to static but can be shifted with TRBL values.
  - ▶ Absolute – location is directly based on TRBL values **within its parent!**
  - ▶ Fixed – location is locked in place.
  - ▶ Sticky – position changes between relative and fixed on scrolling.

## Layout-based styles

15

- ▶ **Top, right, bottom, and left** (TRBL) can be set, but their behavior depends on the position type.
  - ▶ No effect on static position.
  - ▶ Think of this as a Cartesian plane grid, with the top-left corner being (0,0) in terms of (left,top).
  - ▶ You can start from any corner though! Use either T or B, and either L or R.

## Layout-based styles

16

- ▶ In addition to position, another way to affect layout is with **display**.
- ▶ There are several possible values for this but the most important ones for now are:
  - ▶ Block – takes up entire row.
  - ▶ Inline-block – can be placed in row.
  - ▶ None – not added to page.

## Layout-based styles

17

- ▶ If you want to place elements side by side, then try inline-block.

Block display

Inline-block display

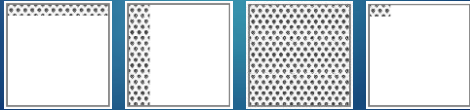

## Layout-based styles

18

- ▶ Positioning and creating layouts with CSS can be complex.
- ▶ We will discuss this topic in more detail next week.
- ▶ For now we are still going through the basics of CSS styles.

## Appearance-based styles 19

- ▶ Background can be a solid colour, gradient, transparent, or an image.
- ▶ For a texture/image, you can also set whether it should be repeated (tiled), its size, and position.

## Appearance-based styles 20

- ▶ Font colour can be any solid color.
- ▶ Border styles have 3 parts:
  - ▶ Colour
  - ▶ Width
  - ▶ Line type (solid, dotted, etc.)

## Appearance-based styles 21

- ▶ Corners can be square or rounded.
- ▶ Rounding values are usually in px.
- ▶ If you use really high rounding values, you can create a circle ☺
  - ▶ If width = height and the rounding value is **at least** half of that width.

## Colours 22

- ▶ Several style types are based on colour (i.e. background colour, font colour, border colour).
  - ▶ They can be hexadecimal or RGB codes. A lot of popular colours can also be called by name! Transparent is another option.
  - ▶ <http://www.html-color-names.com/color-chart.php>

## Style examples 23

- ▶ How are styles actually set?
  - ▶ *property; value;*
- ▶ Examples:
  - ▶ width: 200px;
  - ▶ display: block;
  - ▶ position: absolute;

## Style examples 24

- ▶ Colour examples:
  - ▶ background-color: beige;
  - ▶ background-color: #9595AA
  - ▶ color: yellow;
  - ▶ color: #37B182
  - ▶ color: rgb(255,32,175)
- ▶ What is color vs. background-color?

## Style examples

25

- ▶ Border examples:
  - ▶ border: solid 2px darkred;
  - ▶ border: rgb(0,0,50) dotted 1px;
  - ▶ border-bottom: solid 1px #A744B9;
  - ▶ border-width: 4px;
  - ▶ border-top-color: purple;
- ▶ Lots of flexibility with borders!

## Selectors

26

- ▶ Now that we know how to make individual styles, how do we group them and apply them?
- ▶ A **rule-set** is a group of styles for a certain selector or selectors.
- ▶ There can be any number of styles within a rule-set.

## Selectors

27

- ▶ Wait, what are selectors?
- ▶ Selectors are ways of determining which element(s) are given the styles of the rule-sets.
- ▶ We're essentially indicating which element(s) we want to apply a style to and then using any combination of rules to create the overall style.

## Selectors

28

- ▶ Rule-sets are formatted like:
  - ▶ 

```
selector {
  property1: value1;
  property2: value2;
  ...
}
```
  - ▶ This will make more sense when you see the selectors.
  - ▶ property1: value1 represents a generic property-value style rule.

## Selectors

29

- ▶ There are 3 main types of selectors.
  - ▶ Based on tag / element type.
  - ▶ Based on class name.
  - ▶ Based on ID.
- ▶ There are additional types based on the state of the element, known as pseudo-classes.

## Tag selectors

30

- ▶ Tag selectors apply to **all** elements of the specified HTML tag.
  - ▶ i.e. <p>, <h1>, <body>, <img>
- ▶ These selectors are labelled with the tag name, as it is in HTML, but without the <> brackets.
  - ▶ i.e. p, h1, body, img

## Tag selectors

31

- ▶ `p {`  
    `color: red;`  
    `}`
- ▶ `body {`  
    `margin: 0;`  
    `}`
- ▶ `div {`  
    `background-color: #ff0000;`  
    `}`

## Class selectors

32

- ▶ Class selectors apply to **all** elements that are given the specified class.
- ▶ HTML elements can be given a class as an attribute.
  - ▶ i.e. `<div class='myclass'>`
- ▶ Classes can be applied to any number of elements and any combination of element types.

## Class selectors

33

- ▶ These selectors in CSS are labelled with a period (.) followed by the specific class name it applies to.
  - ▶ i.e. `.myclass`, `.anotherclass`
- ▶ Ensure the class name is spelled identical in HTML and CSS.
  - ▶ i.e. `<div class='my-class'>` will not match the selector `.myclass`

## Class selectors

34

- ▶ `.my-class {`  
    `position: relative;`  
    `}`
- ▶ `.nav {`  
    `margin: 5px;`  
    `color: darkblue;`  
    `width: 100%;`  
    `height: 50px;`  
    `}`

## ID selectors

35

- ▶ ID selectors apply to the element with that ID (if there is one).
- ▶ Just like classes, HTML elements can be given an ID as an attribute.
  - ▶ i.e. `<div id='menu'>`
- ▶ Unlike classes, IDs must be **unique** and not given to multiple elements.
  - ▶ This is important!

## ID selectors

36

- ▶ These selectors in CSS are labelled with a pound sign (#) followed by the specific ID name it applies to.
  - ▶ i.e. `#menu`, `#profile-picture`
- ▶ Ensure the ID name is spelled identical in HTML and CSS.
  - ▶ i.e. `<div id='topmenu'>` will not match the selector `#menu`

## ID selectors

37

- ▶ #menu {  
height: 100px;  
line-height: 100px;  
background-color: black;  
color: white;  
}
- ▶ #title {  
font-size: 40px;  
}

## Styling web forms

38

- ▶ There are many form input types.
- ▶ How can we apply a style to all/several inputs at once, or all inputs of a certain type at once?
- ▶ input { } applies to all "input" tags.
- ▶ Textarea is not made with an input tag so it will not be affected. ☹
- ▶ Use textarea { } for these fields.

## Styling web forms

39

- ▶ i.e. make all form fields 200px wide.
- ▶ input {  
width: 200px;  
}
- ▶ textarea {  
width: 200px;  
}

## Styling web forms

- ▶ If we want the same styles applied to "inputs" and "textareas", it would be redundant to have two identical rule-sets for the two types.
- ▶ Selectors can be grouped together using a comma to separate them.
- ▶ input, textarea {  
width: 200px;  
}

## Styling web forms

41

- ▶ Grouping rule-sets is not only for form input elements but for any combination of selectors (tags, classes, and IDs).
- ▶ p, input, .longtext, #login {  
width: 200px;  
color: blue;  
}

## Styling web forms

42

- ▶ How about if we want to style one specific type of input field at once?
- ▶ CSS allows us to select based on attribute values as well!
- ▶ Remember most input types are specified by the **type** attribute.
  - ▶ i.e. <input type="text" />
  - ▶ i.e. <input type="radio" />

## Styling web forms

43

- ▶ We can specify an attribute value in square brackets [ ] to select that type for a CSS selector.
- ▶ `input[type=text] { border: solid 2px #FA4949 }`
- ▶ `input[type=submit] { width: 200px; }`

## Styling web forms

44

- ▶ These can also be incorporated in grouped selectors.
- ▶ `input[type=submit], #title, p { color:red; }`
- ▶ `input[type=text], textarea { font-size: 20px; }`

## Adding CSS in webpages

45

- ▶ There are 3 ways of adding CSS to webpages:
  - ▶ Inline – in HTML element attributes.
  - ▶ Internal – in HTML head section.
  - ▶ External – in its own file.

## Inline CSS

46

- ▶ One way to add CSS is directly in HTML tags in the `style` attribute.
- ▶ This can work well for applying a style to a single element and doing so quickly for testing purposes.
- ▶ i.e. `<div style='width: 50%; height:300px'>Welcome</div>`

## Internal CSS

47

- ▶ Inline CSS is generally not a good option since it only applies to one element.
- ▶ To apply styles to an entire page, you can add rule-sets into the head section of the HTML.
- ▶ CSS is meta data!

## Internal CSS

48

- ▶ Within the head, use the `<style>` tag to create a place for CSS and then add the styles in there.
- ▶ Works well for a single page site, or styles that only apply to one page.
- ▶ Definitely better than inline styles.

## Internal CSS

49

```
<head>
<style>
  p { color: red; }
  div {
    width: 300px;
    border: solid 2px red;
  }
</style>
</head>
```

## External CSS

50

- ▶ However, internal CSS is still not completely efficient.
- ▶ Suppose you have a website with multiple pages and want the styles to apply to all pages.
- ▶ The best option is **external** CSS.
- ▶ Store the CSS in its own file(s) and link the webpages to the CSS file(s).

## External CSS

51

- ▶ External CSS is stored in files with the .css extension.
- ▶ Linking these files into HTML pages is very simple:
  - ▶ `<link rel="stylesheet" type="text/css" href="styles.css">`
  - ▶ This is also meta information so it goes in the head section of the HTML.

## External CSS

52

```
index.html
<html>
<head>
  <link rel="stylesheet" type="text/css" href="styles.css">
</head>
<body>

styles.css
body {
  margin: 0;
  padding: 0;
  background-color: cyan;
}

p {
  color: yellow;
}

#main-title {
  font-size: 45px;
}
```

## CSS rules

53

- ▶ Styles are applied in top-to-bottom order generally.
- ▶ This only matters if there are conflicting rules or rule-sets.
- ▶ The order doesn't matter otherwise.
- ▶ `p {color: red; width: 50px; }` is the same as `p {width: 50px; color: red; }` since the rules are independent.

## CSS rules

54

- ▶ So where does the order matter?
  - ▶ Conflicting rules within a rule-set.
  - ▶ Multiple rule-sets with conflicting styles applied to an element.
- ▶ Let's look at examples of each.

## CSS rules

55

- ▶ In cases of conflicting rules within a rule-set, the bottom-most rule overrides previous ones.
- ▶ 

```
p {
  color: red;
  color: blue;
}
```
- ▶ In this case, **color: blue** is applied only. It overrides color: red;

## CSS rules

56

- ▶ When multiple rule-sets are applied, it's a little more complicated.
- ▶ 

```
p { color: red; }
.home { color: blue; }
```
- ▶ 

```
<p class='home'>Hello world</p>
```
- ▶ Does the text turn red because it's a paragraph or blue because it has the 'home' class applied to it?

## CSS rules

57

- ▶ The class rule-set takes precedence so the text will be blue.
- ▶ How about if there is an ID too?
- ▶ 

```
p { color: red; }
.home { color: blue; }
#title {color: green; }
```
- ▶ 

```
<p class='home' id='title'>Hello
world</p>
```

## CSS rules

58

- ▶ The ID rule-set will be applied so the text will be green.
- ▶ Why does this happen?
- ▶ CSS rules are assigned a **specificity** or a priority weighting to indicate the precedence in cases of conflicting rules or rule-sets.

## CSS rules

59

- ▶ The specificity order (low to high) is:
  1. Type selectors (p, div, etc.)
  2. Class selectors (.home, etc.)
  3. ID selectors (#title)
- ▶ This is why class overrode type, and ID overrode both type and class in our examples.

## CSS rules

60

- ▶ There's a way to break the regular order of rule-set specificity.
- ▶ The word **!important** immediately after a style gives it top priority.
  - ▶ 

```
p {
  font-size:24px !important;
}
```
- ▶ It's not recommended to use this unless you absolutely need to.

## Design tips

61

- ▶ Tips on smart website design:
  - ▶ Use web-safe fonts or Google Fonts.
  - ▶ Create a consistent and cohesive design for your website.
  - ▶ Limit the number of colours you use.
  - ▶ Ensure all text is readable.
  - ▶ Avoid having tons of text.
  - ▶ Do not center paragraphs of text.

## Design tips

62

- ▶ UI/UX (user interface / experience) means design the site to be intuitive and user-friendly; some users are new to computers.
- ▶ Attract users with beautiful but simple designs.
- ▶ [Eye Tracking Studies](#)
  - ▶ Not required, but interesting to see!

## Design tips

63

- ▶ Web development is often split into two categories: [front-end](#) and [back-end](#).
- ▶ Front-end deals with the design.
- ▶ Back-end deals with the server system and functionalities.
- ▶ [Full-stack](#) is the combination of front and back end development.

## Additional tips

64

- ▶ While creating a website, use flashy backgrounds or borders to help see where elements start and end. I often use reds and yellows to help with this.
- ▶ Once they are in the correct place, revert them to the colours you desire.

## Additional tips

65

- ▶ Sometimes you will change CSS but the change is not displayed when you refresh the browser.
- ▶ Might be due to [cache](#). Browsers save website information so that it can load quicker the next time.
- ▶ To get around this, close Chrome and then open it in Incognito mode.
